Facts for Co	Consideration	
psychological comfort, they dentist may al management.	ntal treatment, patients may have difficulty understanding the procedure and/orical issues, a cognitive, physical or medical disability, or fear and anxiety. Concey may benefit from behavior management through communication techniques y also identify the need for sedation medication and anesthesia for the patient' ent. Anesthesia is a method of providing medication to reduce patient anxiety, and reduction or elimination of pain associated with surgery or treatment.	ensidering patient safety and sor immobilization. In addition, the s comfort and behavior
comfort during anesthesia, is on the patient	ay require local anesthesia, light to moderate conscious sedation, deep sedation ring the performance of dental restorations or surgical procedures. The depth of its a matter of degrees beginning at a low level called "light" and adjusted to tent's tolerance for the procedure and discomfort. Your dentist will recommend might be appropriate for your individual medical/dental needs.	of anesthesia, except for local lighter or deeper levels depending
Patient's initia	nitials required	
Option 1:	: Local Anesthesia	
	Anesthetizing agents, (medications) are injected into a small area with the receive dental treatment. They also can be injected near a nerve to act at to a larger area of the mouth beyond just the site of injection.	<u> </u>
	Risks include but are not limited to: It is normal for the numbness to take usually two or three hours. This can vary depending on the type of medic cases, it can take longer, and in some rare cases, the numbness can be Infection, swelling, allergic reactions, discoloration, headache, tendernes nausea, vomiting, and cheek, tongue, or lip biting can occur.	cation used. However, in some permanent if the nerve is injured.
	<i>Potential benefits:</i> The patient remains awake and can respond to directi or eliminated during the dental treatment.	ions and questions. Pain is lessened
Option 2:	: Nitrous Oxide/Oxygen Inhalation Sedation	
	Nitrous oxide/oxygen (N2O) inhalation is a mild form of conscious seds patient. The patient is observed while N2O is administered and after the patient is fully recovered from its effects.	

Anesthesia 7/2014 Page 1 of 4

	Risks include but are not limited to: An early effect may be disorientation and temporary numbness and tingling. Nausea and vomiting may occur infrequently. If the patient will not accept wearing the N2O mask during treatment, nitrous oxide/oxygen cannot be used.
	Potential benefits: The patient remains awake and can respond to directions and questions. N2O helps overcome apprehension, anxiety, or fear.
Option 3:	Conscious Sedation
	Conscious sedation is a controlled; drug induced, minimally depressed level of consciousness or awareness that allows the patient to breathe independently and continuously respond appropriately to physical stimulation and/or verbal command, e.g., "open your eyes."
	Local anesthetic is still required to numb the area of treatment. This type of anesthesia may be administered orally (a drink or a pill), injected into a muscle, or via a needle inserted into a vein.
	Risks include but are not limited to: Infection, swelling, discoloration, bruising, headache, tenderness at the needle site and vein (phlebitis), dizziness, nausea, and vomiting can occur. Adverse reactions to medication including allergic and life-threatening reactions are possible, though rare. Complications may require hospitalization or even result in brain damage or death. With any patient, reflexes are delayed. Children: Patients can have an immediate response to oral conscious sedation similar to being upset before the medication calms them. Adults: Patients must not drive a car or operate machinery for 24 hours after the termination of treatment, because the effects of sedation remain in the system even after the patient is awake and mobile.
	Potential benefits: Pain is lessened or eliminated during dental treatment. Stress and anxiety can be greatly reduced and often there is no memory of the treatment.
Option 4:	Deep Sedation
	Deep sedation is a controlled, drug-induced state of depressed consciousness or awareness from which the patient is not easily aroused, which may be accompanied by a partial loss of protective reflexes, including the ability to breathe without assistance and/or respond to physical stimulation or verbal command.
	Local anesthetic is still required for numbness to the area of treatment. This type of anesthesia is often called a light general anesthesia and is usually administered in a dental office setting.
	Risks include but are not limited to: Infection, swelling, discoloration, bruising, and tenderness at the needle site (phlebitis) may occur. Dizziness, nausea, and vomiting can occur. Adverse reactions to medication including allergic and life-threatening reactions are possible though rare. Complications may require hospitalization or even result in brain damage or death. A responsible escort must bring the patient to the office, take the patient home, and stay with them. Patients must not drive a car or operate machinery for 24 hours because the effects of the sedative remain in the system even after the patient is awake and mobile.
	Potential benefits: Pain can be lessened or eliminated during the dental treatment. Stress and anxiety can be areatly reduced and often there is no memory of the treatment.

Option 5:	General Anesthesia
	General anesthesia is a controlled, drug-induced state of unconsciousness or lack of awareness, accompanied by partial or complete loss of protective reflexes, including an inability to breathe without assistance, and/or respond purposefully to physical stimulation or verbal command.
	This type of anesthesia is usually administered in a hospital or a surgery center. Local anesthesia is still typically utilized.
	Risks include but are not limited to: Infection, swelling, discoloration, bruising, and tenderness at the needle site (phlebitis) may occur. Dizziness, nausea, and vomiting can occur. Adverse reactions to medication including allergic and life-threatening reactions are possible though rare. Complications may require hospitalization or even result in brain damage or death. A responsible escort must bring the patient to the office, take the patient home, and stay with them. Patients must not drive a car or operate machinery for 24 hours because the effects of sedation remain in the system even after the patient is awake and mobile.
	Potential benefit: Pain is eliminated and the patient has no memory or recall of the surgical procedure.
Alternative	Treatments, Not Limited to the Following:
	If a particular level of anesthesia does not relieve the patient's anxiety or pain, in the dentist's clinical judgment, and if the individual patient can tolerate it, another level of anesthesia may be needed. Not every dental office or dentist is equipped or trained to administer every type of anesthesia. It may be necessary to refer the patient to another facility or to another dentist who has the appropriate equipment or credentials, or an anesthesiologist may be utilized in the office. Those types of services may result in additional charges.
For All <u>Fem</u>	<u>ale</u> Patients
	Because anesthetics, medications and drugs may be harmful to the unborn child and may cause birth defects or spontaneous abortion, every female must inform the provider of anesthesia if she could be or is pregnant. Anesthetics, medications and drugs may affect the behavior of a nursing baby. In either of these situations, the anesthesia and treatment may be postponed.
For All Patie	ents
	I have been given the opportunity to ask questions about the recommended method of anesthesia and believe that I have sufficient information to give my consent as noted below.
